MAS6510

Capacitive Sensor Signal Interface IC

- **Single or Dual Capacitance Sensors**
- **Very Low Power Consumption**
- **On Chip Temperature Sensor**
- **VDD Level Monitoring**
- **24-Bit Ratiometric ΔΣ CDC**
- **EEPROM Calibration Memory**
- **SPI or I2C Bus with programmable I2C device address**

DESCRIPTION

MAS6510 capacitive sensor signal Interface IC can interface both single and dual capacitance sensors.

It uses a 24-bit Capacitance-to-Digital Converter (CDC), which employs a delta-sigma (ΔΣ) conversion technique. The output data from the high order ΔΣ-modulator is processed by an on-chip decimator filter, producing a high resolution conversion result. The converter is run by an internal clock oscillator making an external converter clock unnecessary.

The converter input range is programmable to meet various sensor offset and changing capacitance values. At normal clock frequency maximum sensor capacitance is 20pF but up to 160pF value can be reached by using available clock division options.

The measurement resolution depends on the programmed capacitance range and over sampling ratio (OSR) selections.

MAS6510 supports two capacitance measurement modes. The output can be proportional either to capacitance difference (C_S-C_R) or to capacitance ratio (C_S-C_R)/C_S.

The IC is designed especially to meet the requirement for low power consumption, thus making it an ideal choice for battery powered systems. Current consumption values of 50.3 µA with high resolution or 3.5 µA with low resolution, at a conversion rate of one conversion per second, can be achieved.

In addition to measuring capacitance the device has an internal temperature sensor for temperature measurement and temperature compensation purposes. The VDD level monitoring feature is useful especially in battery operated systems. The 256-bit EEPROM memory stores trimming and calibration coefficients on chip.

A serial interface, compatible with a bi-directional 2-wire I2C bus and 4-wire SPI bus, is used for conversion setup, starting a conversion and reading the conversion result.

FEATURES

- Sensor Offset and Gain Adjustment
  - Changing Capacitance Range ΔC 2pF…30pF
  - Internal Offset Capacitance Matrix 0pF…22pF
  - External Capacitance up to 160pF
- Resolution 17.5 bit
- Internal Clock Oscillator
- On Chip Temperature Sensor -40°C...+85°C
- VDD Level Monitoring
- Low Voltage Operation 1.8 V/1.9V…3.6 V
- Low Supply Current: 3.5 µA...50.3 µA
- Conversion Time 5.8ms...82.6ms (12Hz...173Hz)
- Internal 256-bit EEPROM Calibration Memory
- Internal Clock Oscillator
- I2C and SPI Compatible Serial Interface
- QFN-16 Package

APPLICATIONS

- Capacitive Pressure Sensors
- Humidity Sensors
- Medical Devices
- Flow Meters
- Sport Watches
- Altimeter and Barometer Systems
- Mobile and Battery Powered Systems
- Low Frequency Measurement applications
- Current/Power Consumption Critical Systems
- Industrial and Process Control applications in noisy environments

BLOCK DIAGRAM

Figure 1. MAS6510 block diagram

FUNCTIONAL DESCRIPTION

MAS6510 can interface both single and dual capacitance sensors. Single capacitance sensors should be connected between CS and CC inputs. The second capacitor of a dual capacitance sensor should be connected between CR and CC inputs.

A Capacitance-to-Digital Converter (CDC) converts the input capacitances into a 24-bit output word (CODE). The converter front-end can be configured either for capacitance difference (C_S-C_R) or capacitance ratio (C_S-C_R)/C_S measurement mode. The ratio mode offers pre-linearization for sensor signals $C_S(x)$ being proportional to ~1/x such as pressure sensor signals (x=pressure).

Converter resolution is selected by the over sampling ratio (OSR) setting. Higher OSR corresponds to higher resolution but also longer conversion time.

There are two internal 22pF capacitance matrices connected to the CS and the CR inputs. These matrices are used for sensor offset calibration and they are programmable by 8-bit register (86.3fF/step).

The gain is also programmable with 8-bit resolution and it sets input range for sensor changing capacitance $\Delta C = C_{S\ MAX} - C_{S\_MIN}$.

MAS6510 includes an internal temperature sensor for temperature compensation purposes. A multiplexer in the front-end is used to select the external capacitive sensor, the internal temperature sensor or an internal band gap reference voltage in the VDD level monitoring mode.

Trim and calibration coefficients can be stored in the 256-bit EEPROM memory. In normal mode the stored trim values for the oscillator frequency, offset capacitance and gain are automatically read from the EEPROM memory in the beginning of each conversion. However, by using Trimming control register it is also possible to choose taking trimming values from the trimming registers instead of EEPROM.

To avoid modification of the EEPROM by mistake there is an EEPROM write enable bit in the EEPROM Control Register which needs to be set high (1) before any changes can be done to the EEPROM.

MAS6510 has an internal clock oscillator making an external clock unnecessary. To save power it's turned on only when a conversion is running. The frequency is factory trimmed to 200 kHz using a 6-bit register. An external clock, connected to the OSC pin, can however be used when a specific test mode is chosen. This may be necessary when measuring larger capacitances which require a slower clock frequency than which is supported by internal options.

In temperature measurement mode it is necessary to always use a regulated supply voltage. This is achieved by enabling an internal 1.8V voltage regulator. When enabled the internal regulator is automatically turned on during conversion and off when conversion has been finished. Note that the internal regulator should be enabled only in the temperature measurement mode but kept disabled during capacitance and VDD monitoring modes.

FUNCTIONAL DESCRIPTION

In battery operated applications the VDD of the MAS6510 can vary along with battery capacity. In such case the VDD level monitoring feature can be useful to indicate battery level, help choosing between different power modes in the system or even using measured VDD level for compensating VDD dependencies. In the VDD level monitoring mode the on-chip regulator has to be disabled.

Communication with MAS6510 is handled by the serial interface compatible with either a bi-directional 2-wire I2C bus or a 4-wire SPI bus. The XSPI pin is for selecting which bus type is used.

Note: The 2-wire I2C bus of MAS6510 supports only basic I2C bus communication protocol but not for example 10-bit addressing, arbitration and clock stretching features of the I2C bus specification.

The XCLR pin can be used to hard reset the device including the serial communication. Device reset is possible also via serial bus using the reset register.

Connecting VDD triggers internal power on reset (POR) circuit which resets the device.

Despite of on chip power on reset (POR) circuit it is recommended to reset the device manually after every power up to guarantee proper register settings after any VDD rise conditions.

The EOC pin indicates if a conversion has finished and the result is ready to be read from the memory via the serial interface. Using the EOC signal is not necessary since it is alternatively possible to wait at least maximum conversion time period before reading out the result.

ABSOLUTE MAXIMUM RATINGS

All Voltages with Respect to Ground

Parameter	Symbol	Conditions	Min	Max	Unit
Supply Voltage	V_{DD}		-0.3	5.0	V
Voltage Range for All Pins			-0.3	V_{DD} + 0.3	V
Latch-Up Current Limit	I_{LU}	For all pins, test according to JESD78A.	-100	+100	mA
Junction Temperature	T_{Jmax}			+ 150	°C
Storage Temperature	T_S	Note 1	- 55	+125	°C
ESD Rating	V_{HBM}	Note 2	±1		kV
	V_{CDM}	Note 3	±500V		V

Note: The absolute maximum rating values are stress ratings only. Functional operation of the device at conditions between maximum operating conditions and absolute maximum ratings is not implied and EEPROM contents may be corrupted. Exposure to these conditions for extended periods may affect device reliability (e.g. hot carrier degradation, oxide breakdown). Applying conditions above absolute maximum ratings may be destructive to the devices.
Note: This is a CMOS device and therefore it should be handled carefully to avoid any damage by static voltages (ESD).
Note 1: See EEPROM memory data retention at hot temperature. Storage or bake at hot temperatures will reduce wafer level trimming and calibration data retention time.
Note 2: JEDEC document JEP155 states that 500V HBM allows safe manufacturing with a standard ESD control process.
Note 3: JEDEC document JEP157 states that 250V CDM allows safe manufacturing with a standard ESD control process.

RECOMMENDED OPERATION CONDITIONS

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
Supply Voltage	V_{DD}	Capacitance and VDD level monitoring modes Note 1	1.8	2.7	3.6	V
		Temperature mode Note 1	1.9	2.7	3.6	V
Operating Temperature	T_A		-40	+25	+85	°C
EEPROM Write Temperature	T_A	Note 2	+10	+25	+40	°C

Note 1. In capacitance measurement and VDD level monitoring the regulator must be disabled (TEMPREGEN=0) which allows operation down to 1.8V. In temperature measurement the typ 1.8V regulator has to be enabled (TEMPREGEN=1) which limits the minimum supply voltage down to 1.9V.
Note 2: EEPROM write operation is recommended to be done at room temperature

ELECTRICAL CHARACTERISTICS

Operating Conditions: VDD = 2.7V, T_A = -40°C to +85°C, Typ T_A = 27°C, SOSC=00, unless otherwise specified.

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
Internal regulator voltage	VREG	Temp mode regulator enabled Note 1.	1.75	1.8	1.9	V

Internal system clock oscillator frequency	f_{SYS_CLK}	Normal clock (SOSC=00) Division by 2 (SOSC=01) Division by 4 (SOSC=10) Division by 8 (SOSC=11) TEMPREGEN=0, Note 4	150	200 100 50 25	220	kHz
		Normal clock (SOSC=00) TEMPREGEN=1, Note 4	150	180	210	kHz
Sensor excitation frequency	MCLK	Normal clock (SOSC=00) Division by 2 (SOSC=01) Division by 4 (SOSC=10) Division by 8 (SOSC=11) TEMPREGEN=0	37.5	50 25 12.5 6.25	52.5	kHz
Capacitance and VDD monitoring conversion time	t_{CONVCV}	Normal clock (SOSC=00) OSR=4096 OSR=2048 OSR=1024 OSR=512 OSR=256 TEMPREGEN=0		82.6 41.6 21.1 10.9 5.8	110 55.5 28.2 14.5 7.68	ms
Temperature conversion Time	t_{CONVT}	Normal clock (SOSC=00) OSR=256 TEMPREGEN=1		6.4	7.68	ms

Note 1. Internal regulator must to be enabled only in temperature mode and should be disabled in capacitance and VDD monitoring modes.

Note 2. Leakage current may increase if digital input voltages are not close to VDD (logic level high) or GND (logic level low). Also setting XCS low activates the EEPROM memory regardless of the XSPI setting and the device consumes 20µA …30µA current. To minimize current consumption XCS should be set low only during time periods when the device is used during SPI communication.

Note 3. Conversion current consumption values are measured using CS=CR=7.33pF (CS and CR capacitor matrix registers E3/63$_{HEX}$ and E4/64$_{HEX}$ have value 55$_{HEX}$)

Note 4. The clock oscillator is factory calibrated. Calibration stored in the Oscillator frequency trim data EEPROM address (C6/46$_{HEX}$).

	T_{LSB}			0.001		°C/ LSB
VDD voltage resolution		VDD level monitoring TEMPREGEN=0 OSR=256 Note 4		123		µV$_{RMS}$

Note 1. In capacitance difference mode the maximum allowed sensor and reference capacitor values can be extended further using lower external oscillator frequency than which is available by SOSC division options; C_{S_MAX}=20pF*200kHz/f$_{OSC\_EXT}$.
Note 2. In capacitance ratio mode also larger capacitances are possible depending on sensor characteristics. Please contact Micro Analog Systems to check sensor suitability.
Note 3. Guaranteed by design. By first order calibration of offset and slope an overall temperature accuracy close to the linearity accuracy can be achieved. Further accuracy can be achieved by second order calibration to reduce non-linearity errors. Minimum and maximum values of temperature sensor gain and offset are guaranteed by design.
Note 4. In case of noisy power supply the VDD level monitoring resolution can be further limited by supply noise.

ELECTRICAL CHARACTERISTICS

Operating Conditions: VDD = 2.7V, T_A = -40ºC to +85ºC, Typ T_A = 27ºC, SOSC=00, unless otherwise specified.

OPERATING MODES

MAS6510 has two capacitance measurement modes, a temperature measurement mode and a VDD level monitoring mode. In capacitance measurement mode the output is proportional to either capacitance difference (C_S-C_R) or to capacitance ratio (C_S-C_R)/C_S. In temperature measurement mode the output is proportional to the absolute temperature. The VDD level monitoring mode allows measuring supply voltage which can be useful especially in battery operated systems.

Measurement mode configuration and start of conversion is done by writing 8-bit configuration data to the Measurement control register (address E2$_{HEX}$). See further details in the Measurement control register chapter.

MAS6510 includes a 256-bit EEPROM memory for storing trim and calibration data on chip. Five bytes (40 bits) of EEPROM are reserved for trim values and programmable I2C device address but the remaining 27 bytes (216 bits) are free for storing sensor calibration and other data.

The stored trim data consists of capacitive front-end offset and gain setting data that are automatically read from EEPROM memory in the beginning of each conversion (in normal operating mode). The programmable I2C device address is read from EEPROM memory only during power on reset or by manual reset using XCLR or the reset register.

The stored calibration data should comprise of calibration and temperature compensation coefficients that can be used to calculate accurate sensor and temperature measurement results from the non-calibrated measurement readings. All calculations need to be done in an external micro controller unit (MCU) which controls the MAS6510.

A calibrated MAS6510 sensor system should be operated as illustrated in figure 2. Connecting VDD triggers power-on-reset (POR) but to make sure the device is reset an additional reset should be given using the XCLR pin or writing any data on the reset register E0/60$_{HEX}$ via the serial bus.

The calibration and compensation coefficients are necessary to be read to the MCU memory only once. From each pair of sensor and temperature measurement readings and using the calibration coefficients the accurate sensor and temperature values can then be calculated in the external MCU.

All communication with MAS6510 is done using either the I2C bus or the SPI bus. Starting an A/D conversion, reading the conversion result and reading and writing data from and to the EEPROM memory are all accomplished via serial bus communication.

In addition to the serial buses the digital interface includes also end-of-conversion (EOC) and master reset (XCLR) pins. See A/D Conversion in the Serial Data Interface (I2C Bus) Control chapter.

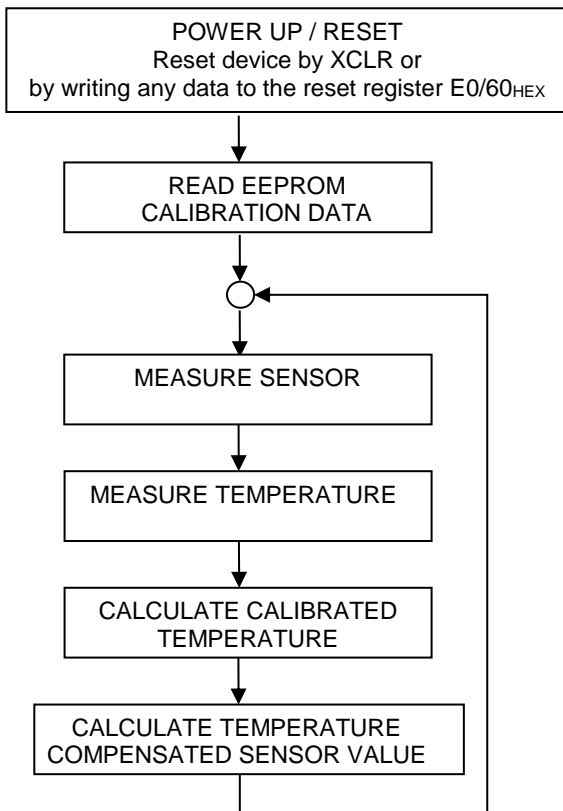

Figure 2. Flow chart for a calibrated MAS6510 sensor system

X = 0 or 1, E = EEPROM, R= Register, T = Trim data

Note: When using the SPI serial interface the register address bit A7 is also used for selecting write (A7= 0) or read (A7=1) operation. For the I2C interface address bit A7 = 1.
Note: The programmable I2C device address register $C2_{HEX}$ has been factory programmed to value EC $_{HEX}$ (%11101100) which is the same as the hard wired device address of MAS6510. When unique device address is needed it can be programmed to this register.

REGISTER AND EEPROM DATA ADDRESSES

MAS6510 includes a 32 byte (256 bit) EEPROM data memory and fourteen registers. Five bytes (40 bits) of EEPROM are reserved for trim values and programmable I2C device address but the remaining 27 bytes (216 bits) are free for storing sensor calibration and other data. See table 1 on the previous page for register and EEPROM data addresses.

In the SPI serial bus the address bit A7 selects between write (A7=0) and read (A7=1) operation. In the I2C serial bus A7 is always high (A7=1) and selection between write and read operation is done with the LSB bit of the I2C device address. See table 11 in chapter SERIAL DATA INTERFACE CONTROL. The MAS6510 has both hard wired and programmable I2C device addresses. The programmable device address is factory programmed to value EC $_{HEX}$ (%11101100) which is the same as the hard wired device address of MAS6510. When unique device address is needed it can be programmed to the Programmable I2C Device Address register (C2$_{HEX}$). The MAS6510 will respond to both hard wired and programmed I2C device addresses.

MAS6510 has four trim registers: C_{S_INT} capacitor matrix register (E3/63$_{HEX}$), C_{R_INT} capacitor matrix register (E4/64$_{HEX}$), Gain register (E5/65$_{HEX}$) and Oscillator frequency control register (E6/66$_{HEX}$). These are marked with "R+T" in table 1. Each of these registers has a corresponding EEPROM byte where trim values can be permanently stored. These are marked with "E+T" in table 1. Trim values are automatically read from EEPROM in the beginning of each conversion when this feature is enabled in the trimming control register (EE/6E$_{HEX}$). When disabled it is possible to test different trim data in the trim registers before final trimming values are found and stored in the EEPROM.

Reset register (E0/60$_{HEX}$) does not contain any data. Any dummy data written to this register forces a reset. A reset initializes all control registers (addresses E1$_{HEX}$…EE$_{HEX}$) to a zero value.

Test register (E1/61$_{HEX}$) is mainly used for testing and trimming purposes. See table 2 in chapter TEST REGISTER. If an external clock signal is used the test register is needed for selecting the external clock signal.

The Measurement control register (E2/62$_{HEX}$) is used for configuring and starting an A/D conversion.

The C_{S_INT} (E3/63$_{HEX}$) and the C_{R_INT} (E4/64$_{HEX}$) capacitor matrix registers select internal capacitors which are connected from CC pin to the CS and to the CR pins respectively. Both matrix capacitor values can be chosen independently between 0pF and 22pF in 86.3fF steps.

The Gain register (E5/65$_{HEX}$) controls the gain of the CDC front-end. Gain value together with the C_{S_INT} and C_{R_INT} values determine input capacitance conversion range.

The Oscillator frequency control register (E6/66$_{HEX}$) is used only during internal clock oscillator trimming. During trimming there is searched register value which gives closest to the nominal 200 kHz oscillator frequency. However the internal clock oscillator frequency is trimmed by MAS during wafer level testing and the trimming value is stored into the Oscillator frequency trim data EEPROM address (C6/46$_{HEX}$). Thus there is no need to adjust the factory stored clock oscillator trimming value. In normal operation the trim value is automatically read from the EEPROM memory in the beginning of each conversion.

EEPROM write enable register (E9/69$_{HEX}$) is used for enabling EEPROM write since by default the EEPROM is write protected.

The 24-bit A/D conversion result (capacitance or temperature) is stored into three registers EA$_{HEX}$ (MSB, most significant byte), EB$_{HEX}$ (ISB, intermediate significant byte), EC$_{HEX}$ (LSB, least significant byte).

The EEPROM status register (ED/6D$_{HEX}$) reflects the EEPROM error correction status. This register can be used to verify that the EEPROM operation has finished without errors.

The Trimming control register (EE/6E$_{HEX}$) defines whether the trim data in the EEPROM or in the registers are used during operation. The default setting is that all trim data is automatically read from the EEPROM memory in the beginning of each conversion. See the Trimming control register description for details.

RESET REGISTER (E0/60$_{HEX}$)

This register is used to reset all control registers (addresses E1$_{HEX}$…EE$_{HEX}$) to a zero value. There are no data bits in this register. However, it is necessary to write dummy data to this register to make a reset.

The reset will take place immediately after any data has been written to the address E0/60$_{HEX}$ via the I2C or SPI interface.

TEST REGISTER (E1/61$_{HEX}$)

In normal operation the Test register value is 00$_{HEX}$ and the internal clock oscillator frequency 200 kHz is used for all the measurements.

FOSC can be used to force the internal oscillator to be on all the time. This is for internal oscillator trimming purpose only. Normally (FOSC=0) the internal oscillator is turned on only during the measurements to save power and the OSC pin output is at logic low. To get the internal 200 kHz clock signal out from OSC pin it is necessary to set FOSC=1.

The SEL_EXTCLK bit selects between internal clock oscillator (OSC pin as digital output) and external clock signal (OSC pin as digital input). External clock selection may come necessary if the sensor capacitance is too high to be used with the internal 200 kHz or divided clock frequency options (see SOSC bits in table 2). The maximum external clock frequency depends on maximum sensor capacitance; $f_{EXT}=200kHz*20pF/C_{S\_MAX}$. Note that if SEL_EXTCLK=1 is selected the internal oscillator is disabled and OSC pin acts as digital input despite of FOSC selection.

The STEST bits are used for connecting different internal signals to the TEST1 and TEST2 pins. In STEST=101 test setup TEST1 and TEST2 operate as positive and negative voltage inputs respectively which are connected to the differential input of the ΔΣ-ADC.

By setting the SOSC bits it is possible to optionally divide the internal system clock frequency by 2, 4 or 8. The undivided 200 kHz system clock frequency allows measuring capacitances up to around 20pF but with the maximum division option 8 capacitances up to 160pF. However, note that only sensor base capacitance scales up this much by clock frequency but the maximum changing capacitance range is smaller (see ELECTRICAL CHARACTERISTICS tables).

Note that the frequency division selection SOSC does not apply to OSC pin clock signals. The internal 200 kHz clock signal from OSC pin and the external clock signal applied to OSC pin are not affected by the SOSC divider options.

Table 2. MAS6510 test register (E1/61$_{HEX}$) description

Bit Number	Bit Name	Description	Value	Function
7	-	Not used	X	-
6	FOSC	Forces the oscillator on without conversion	0 1	OSC is on only during conversion OSC is forced on
5	SEL_EXTCLK	Selects external clock	0 1	Internal clock, OSC output (default) An external clock (OSC input) can be connected to OSC and the internal oscillator is disabled
4-2	STEST	TEST1 and TEST2 signal selection	000…100 101 110…111	Reserved for internal testing purpose (TEST1 and TEST2 are outputs) TEST1 and TEST2 as inputs No function
1-0	SOSC	Select system clock frequency	00 01 10 11	f_{SYS_CLK} = 200 kHz f_{SYS_CLK} = 100 kHz (div by 2) f_{SYS_CLK} = 50 kHz (div by 4) f_{SYS_CLK} = 25 kHz (div by 8)

X = Don't care

MEASUREMENT CONTROL REGISTER (E2/62$_{HEX}$)

This register is used to configure and initiate a measurement. See table 3 below. A new conversion is started simply by writing 8-bit configuration data

having SCO=1 to the measurement control register (E2/62$_{HEX}$).

Table 3. Measurement control register (E2/62$_{HEX}$) description

Bit Number	Bit Name	Description	Value	Function
7-5	OSRS	Over Sampling Ratio (OSR) Selection	000 001 010 011 100	OSR = 256 OSR = 512 OSR = 1024 OSR = 2048 OSR = 4096
4	TEMPREGEN	Temperature Mode Regulator Enable	0 1	Voltage regulator disabled Voltage regulator enabled
3	SCO	Start Conversion	0 1	No conversion Start conversion
2-1	SEL	Capacitive/ VDD Monitoring / Temperature Selection	00 01 10 11	External capacitive sensor VDD level monitoring Internal temperature sensor -
0	XRC	Front end function selector	0 1	Ratio converter Difference converter

The OSRS over sampling ratio selection bits choose between five different OSR values. High OSR value corresponds to high resolution but also longer conversion time. See ELECTRICAL CHARACTERISTICS for further details.

The TEMPREGEN bit enables/disables the internal temperature mode voltage regulator. Regulator must be enabled (TEMPREGEN=1) in temperature measurement (SEL=10) but it should be disabled (TEMPREGEN=0) in capacitance and VDD monitoring modes. When enabled the regulator is turned on during conversions and automatically turned off after each conversion to save power. Note also that if in Test register FOSC=1 and if TEMPREGEN=1 the regulator is forced on all the time even when measurement is not running.

The SCO Start conversion bit needs to be set 1 for every new measurement. It is automatically reset to 0 after each measurement.

The SEL sensor selection bits control the front-end multiplexer. It connects either the external capacitive sensor (SEL=00), VDD level monitoring voltage (SEL=01) or the internal temperature sensor (SEL=10) to the $\Delta\Sigma$-converter.

The XRC bit selects between two external capacitive sensor measurement modes. The XRC bit selection does not have any effect on temperature or VDD level monitoring measurements. In Ratio converter mode the output will be proportional to capacitance ratio $(C_S-C_R)/C_S$. In Difference converter mode the output will be proportional to capacitance difference (C_S-C_R).

INTERNAL CS AND CR CAPACITOR MATRIX REGISTERS (E3/63$_{HEX}$ AND E4/64$_{HEX}$)

There are two internal capacitor matrices C$_{S\_INT}$ and C$_{R\_INT}$ that add capacitance in parallel to external sensor capacitor (C$_{S\_EXT}$) and external reference capacitor (C$_{R\_EXT}$) respectively. See application figure 9 on page 30. These offset capacitances are used to adjust the sensor signal to an optimal CDC input range. Each capacitor matrix has a selectable capacitance from 0pF up to 22pF in typical 86.3fF steps. The three sigma process variation of the capacitor matrix capacitance is ±10%.

The C$_{S\_INT}$ capacitor matrix is controlled by 8-bit register (E3/63$_{HEX}$) value OCDACS. See table 4. It has a corresponding EEPROM address (C3/43$_{HEX}$) as non-volatile storage of the trim value. The C$_{R\_INT}$ capacitor matrix is controlled by 8-bit register

(E4/64$_{HEX}$) value OCDACR. See table 5. It has also corresponding EEPROM address (C4/44$_{HEX}$) as non-volatile storage of the trim value. The internal C$_{S\_INT}$ and C$_{R\_INT}$ capacitor matrix capacitance values depend on OCDACS and OCDACR register values according to equations 1-2.

After finding suitable C$_{S\_INT}$ and C$_{R\_INT}$ capacitor matrix register values the trim values can be stored in the corresponding non-volatile EEPROM addresses.

In normal operating mode these trim values are automatically read from the EEPROM during each conversion start. See also table 10 Trimming control Register (EE/6E$_{HEX}$) for other operating modes.

$$C_{S\_INT} = 22\,pF \cdot \frac{OCDACS}{255}$$ **Equation 1.**

$$C_{R\_INT} = 22\,pF \cdot \frac{OCDACR}{255}$$ **Equation 2.**

Table 4. C$_{S\_INT}$ internal capacitor matrix register (E3/63$_{HEX}$), EEPROM address (C3/43$_{HEX}$)

Bit Number	Bit Name	Description	Value	Function
7-0	OCDACS	CDAC control bits	00$_{HEX}$…FF$_{HEX}$	C$_{S\_INT}$ offset trimming

Table 5. C$_{R\_INT}$ internal capacitor matrix register (E4/64$_{HEX}$), EEPROM address (C4/44$_{HEX}$)

Bit Number	Bit Name	Description	Value	Function
7-0	OCDACR	CDAC control bits	00$_{HEX}$…FF$_{HEX}$	C$_{R\_INT}$ offset trimming

GAIN REGISTER (E5/65$_{HEX}$)

The 8-bit gain register (E5/65$_{HEX}$) value (GRDAC) adjusts excitation signal level for the capacitive sensor. See table 6. Larger register value corresponds to smaller input changing capacitance range and vice versa. The gain register together with the C$_{S\_INT}$ and the C$_{R\_INT}$ capacitor matrix trim parameters define input capacitance range of measurement. Ideally the sensor signal is fit perfectly within the linear input capacitance range of

the CDC. Such trimming maximizes resolution and dynamic range of the measurement.

The gain register (E5/65$_{HEX}$) has a corresponding EEPROM address (C5/45$_{HEX}$) as non-voltage storage of the trim value. After finding a suitable gain register value it can be stored in the non-volatile EEPROM memory. In normal operating mode the gain trim value is read automatically from the EEPROM during each conversion start.

Table 6. Gain register (E5/65$_{HEX}$), EEPROM address (C5/45$_{HEX}$)

Bit Number	Bit Name	Description	Value	Function
7-0	GRDAC	RDAC control bits	00$_{HEX}$…FF$_{HEX}$	Gain adjustment by sensor excitation signal level control

OSCILLATOR FREQUENCY CONTROL REGISTER (E6/66$_{HEX}$)

Note that the internal clock oscillator frequency has been factory trimmed and the trim value has been stored in the EEPROM (C6/46$_{HEX}$). It is recommended not to change the factory programmed value!

The oscillator frequency control register (E6/66$_{HEX}$) is for trimming the internal clock oscillator to 200 kHz frequency. This 200 kHz can be measured at the OSC pin. The six LSB bits adjust the oscillator period in 104ns steps. The period increases when the trim value increases. Typically a register value of 28$_{HEX}$ corresponds to the nominal 200 kHz clock oscillator frequency. After finding a suitable trim value it can be stored to the EEPROM (C6/46$_{HEX}$).

Table 7. Oscillator frequency control register (E6/66$_{HEX}$)

Bit Number	Bit Name	Description	Value	Function
5-0	OSCF	Oscillator frequency control bits	00$_{HEX}$…3F$_{HEX}$	Oscillator frequency control

EEPROM DATA INPUT REGISTER (E8/68$_{HEX}$)

This register can be ignored by user. It is related to internal EEPROM operations and updated automatically during every EEPROM write operation.

EEPROM WRITE ENABLE REGISTER (E9/69$_{HEX}$)

The EEPROM is normally write protected. To enable write the EEPROM write enable register should be set to %00000100 (04$_{HEX}$). To disable write the register should be set to %00000000 (00$_{HEX}$) which is the register default value after power-on-rest or manual reset by XCLR or reset register. Note: don't use any other EEPROM write enable register values than these two since other register bits are reserved for internal testing purpose only.

Table 8. EEPROM write enable register (E9/69$_{HEX}$)

Bit Number	Bit Name	Description	Value	Function
7-3			00000	Reserved. Keep these bits always 0.
2	EWE	EEPROM write enable	0 1	EEPROM write disabled EEPROM write enabled
1-0			00	Reserved. Keep these bits always 0.

After a power-on-reset and in normal operation the EEPROM write enable register has the default value 00$_{HEX}$.

CONVERSION RESULT REGISTERS (EA…EC$_{HEX}$)

After measuring capacitance, temperature or supply voltage the 24-bit conversion result is stored into three register addresses EA…EC$_{HEX}$. The MSB (most significant byte) is at EA$_{HEX}$, ISB (intermediate significant byte) at EB$_{HEX}$ and LSB (least significant byte) at EC$_{HEX}$.

EEPROM STATUS REGISTER (ED/6D$_{HEX}$)

The EEPROM status register (ED/6D$_{HEX}$) indicates if the stored EEPROM byte is corrupted. The register is updated after each EEPROM data byte read command. See table 9 below. The ERROR bit tells whether a data error has been detected or not. The DED bit tells whether two or more bit errors have been detected. The EEPROM can correct internally only single bit errors i.e. when ERROR=1 and DED=0. The read EEPROM data byte is corrupted if ERROR=DED=1.

Table 9. MAS6510 EEPROM status register (ED/6D$_{HEX}$). Only bits (7:6) are used.

Bit Number	Bit Name	Description	Value	Function
7	ERROR	EEPROM error detection	0	No errors
			1	Error detected
6	DED	EEPROM double error detection	0	No errors
			1	2 (or more) data errors
5-0			000000	-

TRIMMING CONTROL REGISTER (EE/6E$_{HEX}$)

The Trimming control register (EE/6E$_{HEX}$) is used to select between different trimming operating modes. See table 10 showing the functions of the Trimming control register.

After a power-up reset, master reset via XCLR or a software reset via serial bus the Trimming control register (EE/6E$_{HEX}$) gets the value %00000000 (00$_{HEX}$). This is the normal operating mode for a trimmed MAS6510 device. In this mode the capacitive front-end trim values to use (CS, CR and Gain) are automatically read from the EEPROM memory in the beginning of each conversion start.

When calibrating a sensor there is an operating mode in which only the factory calibrated internal oscillator (OSC) clock trim data is read from the EEPROM memory. This mode is selected by writing %10101010 (AA$_{HEX}$) to the Trimming control register. In this mode it is possible to run conversion tests for different front-end trim register values before suitable values are found and programmed to the EEPROM.

There is also a trimming mode in which all trim data including the internal oscillator trim data is taken from the trim registers rather than from the EEPROM. This mode is selected by writing %11111111 (FF$_{HEX}$) to the Trimming control register.

Table 10. Trimming control Register (EE/6E$_{HEX}$)

Bit Number	Bit Name	Description	Value	Function
7-0	REGEE<7:0>	EEPROM control bits	00000000	All trim data from EEPROM (normal operating mode)
			10101010	Only OSC from EEPROM
			11111111	All trim data from registers
			OTHER	All trim data from EEPROM

Figure 3. Flow chart for MAS6510 EEPROM write

Important note: Before EEPROM programming make sure that in the Test register (E1/61$_{HEX}$) the SOSC=00 is selected. That selects 200 kHz system clock frequency which is required for the proper EEPROM programming pulses. This condition is guaranteed by making device reset either using the reset register (E0/60$_{HEX}$) or the XCLR pin.
Note: In the "VERIFY WRITTEN DATA" step it could be also additionally checked that the EEPROM status register (ED/6D$_{HEX}$) does not indicate read errors.

EEPROM WRITE PROCEDURE

This chapter gives instructions for writing data to the EEPROM memory.

The MAS6510 24-bit Capacitance-to-Digital Converter (CDC) has a 256 bit (32 byte) EEPROM memory. 8 bits (1 byte) has been reserved for storing internal clock oscillator trimming data and other 8 bits (1 byte) for the programmable I2C device address. There are also 24 bits (3 bytes) for trimming the capacitive sensor front-end. The remaining 216 bits (27 bytes) are free for storing sensor calibration data and other use.

See figure 3 on previous page showing the EEPROM write procedure.

Make sure in the beginning of the EEPROM write procedure that the MAS6510 initial conditions are met. Connecting VDD triggers power-on-reset (POR) but to make sure the device is reset an additional reset should be given using the XCLR pin or writing any data on the reset register E0/60$_{HEX}$ via the serial bus. The device reset will guarantee that SOSC=00 is selected in the test register (E1/61$_{HEX}$).

This selects 200 kHz clock which is required in the EEPROM programming.

EEPROM write is enabled by writing value 04$_{HEX}$ to the EEPROM write enable register (E9/69$_{HEX}$). The default register value after power on is 00$_{HEX}$.

Next the data can be written to the EEPROM memory one byte (8-bit) at a time. It is necessary to have a delay of minimum 16ms after programming each byte (8-bit). The success of each write can be verified by reading back the data (8-bit) and comparing it to the original byte (8-bit). Additionally, it is also possible to check the EEPROM status register (ED/6D$_{HEX}$) value after each read back. The EEPROM status register value should be 00$_{HEX}$ when the read EEPROM data byte is free of errors.

After all data bytes are written the EEPROM memory can be protected from write by writing 00$_{HEX}$ to the EEPROM write enable register (E9/69$_{HEX}$).

See table 1 showing the MAS6510 register and EEPROM data addresses.

SERIAL DATA INTERFACE CONTROL

Serial Interface

MAS6510 can be operated either via 2-wire serial I2C bus or via 4-wire serial SPI bus. Selection between I2C and SPI communication is done by XSPI pin. XSPI=high selects I2C and XSPI=low selects SPI communication.

2-wire serial I2C bus type interface comprises of serial clock input (SCL) and bi-directional serial data (SDA) input/output. I2C bus is used to write configuration data to sensor interface IC and read the measurement result when A/D conversion has been finished. The interface is also used for reading the calibration EEPROM memory.

Note: The 2-wire I2C bus of MAS6510 supports only basic I2C bus communication protocol but not for example 10-bit addressing, arbitration and clock stretching features of the I2C bus specification.

The alternative 4-wire serial SPI bus type interface comprises of serial clock input (SCLK), serial data

input (MOSI), serial data output (MISO) and chip select input (XCS).

Digital interface includes also end of conversion (EOC) and master reset (XCLR) pins. Rising edge in the EOC pin indicates that the conversion is ready and the result can be read out through serial interface.

XCLR is used to reset the MAS6510. A reset initializes registers (set to value 00_{HEX}), counters and the serial communication bus. Alternatively, device can be reset via serial bus by writing any data to Reset register (address $E0/60_{HEX}$). The Reset register bits don't have any function. Reading from the reset register is not possible.

After connecting the supply voltage to MAS6510, and before starting operating the device via the serial bus it is recommended to reset the device manually after every power up to guarantee proper register settings after any VDD rise conditions

I2C Bus Communication

In MAS6510 the I2C bus communication is selected by setting XSPI pin high.

The I2C bus standard makes it possible to connect several devices on same bus. The devices are distinguished from each other by unique device addresses. In MAS6510 there is both a hard wired and programmable device address. Both hard wired and programmable addresses can be used to address MAS6510. The MAS6510 hard wired device address is shown in the following table. The LSB bit of the device address defines whether the bus is configured to Read (1) or Write (0) operation.

The programmable device address is located in the EEPROM register $C2_{HEX}$ which has been factory programmed to value EC_{HEX} (%11101100) which is the same as the fixed device address of MAS6510. When unique device address is needed it can be programmed to this register. The programmable I2C device address is read from EEPROM memory only during power on reset or manual reset situations. To guarantee that the programmable address is read from EEPROM the device can be reset manually by using XCLR pin or Reset register ($E0/60_{HEX}$).

Table 11. MAS6510 hard wired I2C bus device address (EC/ED_{HEX})

A7	A6	A5	A4	A3	A2	A1	W/R
1	1	1	0	1	1	0	0/1

I2C Bus Protocol Definitions

Data transfer is initiated with a Start bit (S) when SDA is pulled low while SCL stays high. Then, SDA sets the transferred bit while SCL is low and the data is sampled (received) when SCL rises. When the transfer is complete, a Stop bit (P) is sent by releasing the data line to allow it to be pulled up while SCL is constantly high.

Figure 4 shows the start (S) and stop (P) bits and a data bit. Data must be held stable at the SDA pin

when SCL is high. Data at the SDA pin can change value only when SCL is low.

Each SDA line byte transfer must contain 8-bits where the most significant bit (MSB) always comes first. Each byte has to be followed by an acknowledge bit (see further below). The number of bytes transmitted per transfer is unrestricted.

2-WIRE SERIAL DATA INTERFACE (I2C BUS)
Figure 4. I2C bus protocol definitions
Bus communication includes Acknowledge (A) and not Acknowledge (N) messages. To send an acknowledge the receiver device pulls the SDA low for one SCL clock cycle. For not acknowledge (N)

Abbreviations:
A= Acknowledge by Receiver
N = Not Acknowledge by Receiver
S = Start
Sr = Repeated Start

the receiver device leaves the SDA high for one SCL clock cycle in which case the master can then generate either a Stop (P) bit to abort the transfer, or a repeated Start (Sr) bit to start a new transfer.

P = Stop

▨ = from Master (MCU) to Slave (MAS6510)

☐ = from Slave (MAS6510) to Master (MCU)

Conversion Starting – Write Sequence

Conversion is started by writing configuration bits into the Measurement control register (address E2$_{HEX}$). The write sequence is illustrated in Table 12.

Table 12. MAS6510 I2C bus write sequence of Measurement control register

AR = Device Read Address ED$_{HEX}$ (%1110 1101)
MC = Meas. control register 62$_{HEX}$ (%0110 0010)
Ax = Conversion Result Registers' Addresses; MSB (x=M, 6A$_{HEX}$ %0110 1010), ISB (x=I, 6B$_{HEX}$ %0110 1011) or LSB (x=L, 6C$_{HEX}$ %0110 1100)

DC = Measurement Control Register Data
Dx = Conversion Result Register Data; MSB (x=M), ISB (x=I) or LSB (x=L)

Each serial bus operation, like write, starts with the start (S) bit (see figure 4). After start (S) the MAS6510 device address with write bit (AW, see table 11) is sent followed by an Acknowledge (A). After this the Measurement control register address (see table 1) is sent and followed by an Acknowledge

(A). Next the Measurement control register data (DC, see table 3) is written and followed by an Acknowledge (A). Finally, the serial bus operation is ended with stop (P) command (see figure 4). A new A/D conversion starts right after Measurement control register bits containing SCO=1 are received.

A/D Conversion

After power on reset or external reset (XCLR) the EOC output is high. After an A/D conversion is started the EOC output is set low until the conversion is finished and the EOC goes back high, indicating that the conversion is done and data is ready for reading. The EOC is set low only by starting a new

conversion. To save power the internal oscillator runs only during conversion.
During an A/D conversion the input signal is sampled continuously leading to an output conversion result that is a weighted average of the samples taken.

2-WIRE SERIAL DATA INTERFACE (I2C BUS)

Conversion Result – Read Sequence

Table 13 presents a general control sequence for a single register data read.

Table 13. MAS6510 I2C bus single register (address Ax) read sequence bits

S	AW	A	Ax	A	Sr	AR	A	Dx	N	P

Table 14 shows the control sequence for reading the 24-bit A/D conversion result from the Conversion result registers. The ISB (DI) and LSB (DL) register data read can follow right after the MSB register data (DM) read since if the read sequence is continued (not ended by a Stop bit P) the register address is automatically incremented to point to the next register.

Table 14. MAS6510 I2C bus MSB (first), MID (second) and LSB (third) A/D conversion result read sequence

S	AW	A	AM	A	Sr	AR	A	DM	A	DI	A	DL	N	P

4-WIRE SERIAL DATA INTERFACE (SPI BUS)

SPI bus communication is selected by setting XSPI pin low.

SPI communication differs from I2C bus in the following way. It requires four wires for bi-directional communication since each line operates in one direction only. Device selection is done by using separate chip select XCS control lines instead of using device address. Each SPI bus device has its own XCS control line and a device is selected by pulling its XCS line low (see figure 5 below). The fourth wire in the SPI bus is the serial clock line, SCLK. Data is transferred at rising edges of the serial clock during which the data line should be stable.

The selection between write or read access is done by register address MSB bit A7 (see table 1 "*Register*

and EEPROM data addresses"). In write access bit A7 cleared (0) and in read access it is set (1).

Figure 5 illustrates write access communication. MAS6510 has an auto increment function which means that if there are more than one data byte transferred the additional data bytes are delivered to following register addresses. In write communication the MISO line is high impedance.

In SPI bus communication it is good to note that setting XCS low activates the EEPROM memory regardless of the XSPI setting and the device consumes $20\mu A \dots 30\mu A$ current. To minimize current consumption XCS should be set low only during time periods when the device is used during SPI communication.
Figure 5. *SPI Protocol – Write Access (register address MSB bit A7=0)*

4-WIRE SERIAL DATA INTERFACE (SPI BUS)

Figure 6 illustrates read access communication. The auto increment function can be utilized also in read access and if there are more than one data byte read the additional data bytes are delivered from following register addresses.
Figure 6. *SPI Protocol – Read Access (register address MSB bit A7=1)*

CAPACITANCE MEASUREMENT MODES

MAS6510 has two capacitance measurement modes. Selection between modes is done by XRC bit in the Measurement control register (E2/62$_{HEX}$). Capacitance difference mode is selected by XRC=1 and capacitance ratio mode by XRC=0. See table 3 on page 12.

Capacitance difference mode

In the capacitance difference mode the CDC output result (CODE) is proportional to capacitance difference $\Delta C=(C_S-C_R)$ where the C_S is overall capacitance between CS and CC pins and the C_R is overall capacitance between CR and CC pins. See equation 3.

$$CODE = \frac{CODEFS}{2} \cdot \left[1 + \left(\frac{\Delta C}{C_{REF}} \right) \cdot K_{DIFF} \right] = \frac{CODEFS}{2} \cdot \left[1 + \left(\frac{C_S - C_R}{C_{REF}} \right) \cdot K_{DIFF} \right] \qquad \textbf{Equation 3.}$$

where

CODEFS = Maximum output code range which depends on OSR selection. See page 7 "Full scale output code range" specification in the ELECTRICAL CHARACTERISTICS table.

K_{DIFF} = 0.229+0.02*GRDAC (see table 6 for Gain register setting)		**Equation 4.**
C_{REF} = 6pF ±10%	Internal reference capacitor	
$C_S = C_{S\_EXT} + C_{S\_INT}$	External sensor + internal sensor matrix capacitance between CS and CC pins	**Equation 5a.**
$C_R = C_{R\_EXT} + C_{R\_INT}$	External reference + internal reference matrix capacitance between CR and CC pins	**Equation 5b.**
$\Delta C_{EXT} = C_{S\_EXT} - C_{R\_EXT}$	Capacitance difference of external capacitances	
$\Delta C_{INT} = C_{S\_INT} - C_{R\_INT}$	Capacitance difference of internal offset capacitance matrices	**Equation 5c.**
$\Delta C = (C_S-C_R) = (C_{S\_EXT} + C_{S\_INT}) - (C_{R\_EXT} + C_{R\_INT}) = \Delta C_{EXT} + \Delta C_{INT}$	Overall capacitance difference	**Equation 5d.**

In capacitance difference mode either C_{S_EXT}, C_{R_EXT} or both external capacitances can vary.

Substituting equation 5d to equation 3 lead to equation 6.

$$CODE = \frac{CODEFS}{2} \cdot \left[1 + \left(\frac{\Delta C_{EXT} + \Delta C_{INT}}{C_{REF}} \right) \cdot K_{DIFF} \right] \qquad \textbf{Equation 6.}$$

From equations 5c and 6 we see that offset trimming of the CODE is achieved using internal capacitance matrices which define the $\Delta C_{INT} = C_{S\_INT} - C_{R\_INT}$ term. Increasing C_{S_INT} increases CODE and increasing C_{R_INT} decreases CODE. The C_{S_INT} and C_{R_INT} capacitances are adjusted by OCDACS and OCDACR settings respectively (see Internal capacitor matrix registers in tables 4 and 5). Gain trimming is achieved by gain register GRDAC value (see Gain register in table 6) which adjusts gain coefficient (K_{DIFF}) according to equation 4.

The CDC output result (CODE) ranges from 0 to CODEFS. These correspond to following minimum (ΔC_{EXT_MIN}) and maximum (ΔC_{EXT_MAX}) external input capacitance difference and overall external changing capacitance (ΔC_{EXT_TOT}) values.

$$\Delta C_{EXT\_MIN} = -\frac{C_{REF}}{K_{DIFF}} - \Delta C_{INT} \;,\; \Delta C_{EXT\_MAX} = \frac{C_{REF}}{K_{DIFF}} - \Delta C_{INT} \qquad \textbf{Equations 7a, 7b}$$

$$\Delta C_{EXT\_TOT} = \Delta C_{EXT\_MAX} - \Delta C_{EXT\_MIN} = 2 \cdot \frac{C_{REF}}{K_{DIFF}} \qquad \textbf{Equations 7c.}$$

However linear measurement range of CDC is from 10% to 90% of CODEFS. To avoid non-linearity error in the measurements the capacitive front-end should be trimmed to keep the measured external capacitance within the linear measurement range of the CDC. In the linear measurement range the minimum ($\Delta C_{EXT\_LIN\_MIN}$) and maximum ($\Delta C_{EXT\_LIN\_MAX}$) external capacitance difference and overall external changing capacitance ($\Delta C_{EXT\_LIN\_TOT}$) values are as follows.

CAPACITANCE MEASUREMENT MODES (continued)

$$\Delta C_{EXT\_LIN\_MIN} = -80\% \cdot \frac{C_{REF}}{K_{DIFF}} - \Delta C_{INT} \ , \ \Delta C_{EXT\_LIN\_MAX} = 80\% \cdot \frac{C_{REF}}{K_{DIFF}} - \Delta C_{INT} \qquad \textbf{Equations 8a, 8b.}$$

$$\Delta C_{EXT\_LIN\_TOT} = \Delta C_{EXT\_LIN\_MAX} - \Delta C_{EXT\_LIN\_MIN} = 1.6 \cdot \frac{C_{REF}}{K_{DIFF}} = 0.8 \cdot \Delta C_{EXT\_TOT} \qquad \textbf{Equation 8c.}$$

Example:

GRDAC = 109$_{DEC}$, OCDACS = 0$_{DEC}$ and OCDACR = 93$_{DEC}$ trim settings correspond to following external input capacitance difference measurement range values.

> Capacitance values of offset capacitance matrices:
>
> C_{S_INT} = 22pF*0/255 = 0pF, C_{R_INT} = 22pF*93/255 $\approx$ 8.03pF, ΔC_{INT} = 0pF - 8.03pF = -8.03pF $\Rightarrow$
>
> Gain coefficient: K_{DIFF} = 0.229+0.02*109 = 2.409
>
> Overall input range:
>
> ΔC_{EXT_MIN} = -6pF/2.409-(-8.03pF) $\approx$ 5.54pF
>
> ΔC_{EXT_MAX} = 6pF/2.409-(-8.03pF) $\approx$ 10.52pF
>
> ΔC_{EXT_TOT} = 2*6pF/2.409 $\approx$ 4.98pF
>
> Linear input range:
>
> $\Delta C_{EXT\_LIN\_MIN}$ = -0.8*6pF/2.409-(-8.03pF) $\approx$ 6.04pF
>
> $\Delta C_{EXT\_LIN\_MAX}$ = 0.8*6pF/2.409-(-8.03pF) $\approx$ 10.02pF
>
> $\Delta C_{EXT\_LIN\_TOT}$ = 0.8*4.98pF $\approx$ 3.98pF

Note that above calculated values are capacitance difference values between external sensor (CS) and external reference (CR) side capacitances ($\Delta C_{EXT} = C_{S\_EXT} - C_{R\_EXT}$). If there is no external reference capacitor (C_{R_EXT}=0) then these values represent sensor side (CS) capacitance C_{S_EXT} ($\Delta C_{EXT} = C_{S\_EXT} - 0 = C_{S\_EXT}$) minimum and maximum measurement range values. If a fixed external reference capacitor C_{R_EXT} exists then sensor side (CS) capacitance measurement range is C_{R_EXT} added to above ΔC_{EXT} values ($C_{S\_EXT} = \Delta C_{EXT} + C_{R\_EXT}$). If C_{R_EXT} is also varying then above values tell range of C_{S_EXT} and C_{R_EXT} capacitance difference ($\Delta C_{EXT} = C_{S\_EXT} - C_{R\_EXT}$) that can be measured.

Capacitance ratio mode

In the capacitance ratio mode the CDC output result (CODE) is proportional to capacitance ratio $(C_S-C_R)/C_S$.

$$CODE = CODEFS \cdot \left[1 - \frac{C_R}{C_S} \right] \cdot K_{RATIO} = CODEFS \cdot \left[1 - \frac{C_{R\_EXT} + C_{R\_INT}}{C_{S\_EXT} + C_{S\_INT}} \right] \cdot K_{RATIO} \qquad \textbf{Equation 9.}$$

where

CODEFS = Maximum output code range which depends on OSR selection. See page 7 "Full scale output code range" specification in the ELECTRICAL CHARACTERISTICS table.

K_{RATIO} = 193.8/GRDAC (see table 6 for Gain register setting) $\qquad$ **Equation 10.**

$C_S = C_{S\_EXT} + C_{S\_INT}$ $\qquad$ External sensor + internal sensor matrix capacitance between CS and CC pins
$C_R = C_{R\_EXT} + C_{R\_INT}$ $\qquad$ External reference + internal reference matrix capacitance between CR and CC pins

TRIMMING FOR SENSOR CAPACITANCE

MAS6510 in capacitance difference mode

Optimal trim settings which adjust capacitive signal to linear conversion range 10%...90% of the CDC are calculated as follows. At first offset C_{OFS_EXT} of external capacitance ranges C_{S_EXT} and C_{R_EXT} is calculated.

$C_{OFS\_EXT} = (\Delta C_{EXT\_MIN} + \Delta C_{EXT\_MAX}) / 2 =$

$= (C_{S\_EXT\_MIN} - C_{R\_EXT\_MAX} + C_{S\_EXT\_MAX} - C_{R\_EXT\_MIN}) / 2$ **Equation 11.**

The offset compensated to zero by using either C_{S_INT} or C_{R_INT} capacitor matrices depending on the offset polarity.

If $C_{OFS\_EXT} \geq 0pF$

      then $C_{R\_INT} = C_{OFS\_EXT}$ and $C_{S\_INT} = 0pF$

      else $C_{R\_INT} = 0pF$ and $C_{S\_INT} = -C_{OFS\_EXT}$

Corresponding capacitance matrix register values (decimal) are calculated as follows.

$REG_{E3HEX} = OCDACS = (C_{S\_INT}/22pF)*255_{DEC}$ **Equation 12.**

$REG_{E4HEX} = OCDACR = (C_{R\_INT}/22pF)*255_{DEC}$ **Equation 13.**

Optimal gain coefficient (K_{DIFF}) value scales capacitive signal to linear conversion range 10%...90% of the CDC and it is calculated as follows.

$K_{DIFF} = 1.6*C_{REF} / (\Delta C_{EXT\_MAX} - \Delta C_{EXT\_MIN}) =$

$= 1.6*C_{REF} / (C_{S\_EXT\_MAX} - C_{S\_EXT\_MIN} + C_{R\_EXT\_MAX} - C_{R\_EXT\_MIN})$ **Equation 14.**

where $C_{REF} = 6pF \pm 10\%$.

Corresponding Gain register (REG_{E5HEX}) value (decimal) can be solved from the equation 4 presented on page 22 as follows.

$REG_{E5HEX} = GRDAC = (K_{DIFF}-0.229)/0.02$ **Equation 15.**

Example 1: No external reference capacitor C_{R_EXT}
    $C_{S\_EXT\_MIN} = 8pF$ and $C_{R\_EXT\_MAX} = 0pF$ at sensed parameter (pressure, humidity etc.) minimum
    $C_{S\_EXT\_MAX} = 12pF$ and $C_{R\_EXT\_MIN} = 0pF$ at sensed parameter (pressure, humidity etc.) maximum $\Rightarrow$
    $C_{R\_OFS\_EXT} = (8pF-0pF+12pF-0pF)/2=10pF$
    $C_{OFS\_EXT} \geq 0$ $\Rightarrow$
    $C_{R\_INT} = C_{OFS\_EXT} = 10pF$ and $C_{S\_INT} = 0$ pF
    $K_{DIFF} = 1.6*6pF/(12pF-8pF+0pF-0pF) = 2.4$ $\Rightarrow$
    $REG_{E3HEX} = OCDACS =$ (0pF/22pF)*255 = **0$_{DEC}$ (CS capacitor matrix)**
    $REG_{E4HEX} = OCDACR =$ (10pF/22pF)*255 = 115.91 ≈ **116$_{DEC}$ (CR capacitor matrix)**
    $REG_{E5HEX} = GRDAC =$ (2.4-0.229)/0.02 = 108.55 ≈ **109$_{DEC}$ (Gain register)**

Example 2: Both C_{S_EXT} and C_{R_EXT} vary but to opposite directions
    $C_{S\_EXT\_MIN} = 10pF$ and $C_{R\_EXT\_MAX} = 14.5pF$ at sensed parameter (pressure, humidity etc.) minimum
    $C_{S\_EXT\_MAX} = 14pF$ and $C_{R\_EXT\_MIN} = 10pF$ at sensed parameter (pressure, humidity etc.) maximum $\Rightarrow$
    $C_{OFS\_EXT} = (10pF-14.5pF+14pF-10pF)/2 = -0.25pF$
    $C_{OFS\_EXT} < 0$ $\Rightarrow$
    $C_{R\_INT} = 0pF$ and $C_{S\_INT} = -C_{OFS\_EXT} = 0.25pF$
    $K_{DIFF} = 1.6*6pF/(14pF-10pF+14.5pF-10pF) = 1.129$ $\Rightarrow$
    $REG_{E3HEX} = OCDACS =$ (0.25pF/22pF)*255 = 2.90 ≈ **3$_{DEC}$ (CS capacitor matrix)**
    $REG_{E4HEX} = OCDACR =$ (0pF/22pF)*255 = **0$_{DEC}$ (CR capacitor matrix)**
    $REG_{E5HEX} = GRDAC =$ (1.129-0.229)/0.02 = 45.00 ≈ **45$_{DEC}$ (Gain register)**

The found REG_{E3HEX}, REG_{E4HEX} and REG_{E5HEX} trim register values need to be stored to corresponding non-volatile EEPROM addresses. In I2C communication these are $C3_{HEX}$, $C4_{HEX}$ and $C5_{HEX}$ but in SPI write communication the addresses are 43_{HEX}, 44_{HEX} and 45_{HEX} since in SPI write the MSB address bit is 0. See table 1 on page 9.

TRIMMING FOR SENSOR CAPACITANCE (continued)

MAS6510 in capacitance ratio mode

Optimal trim settings which adjust capacitive signal to linear conversion range 10%...90% of the CDC are found as follows.

C_{OFS} = [0.9*$C_{S\_EXT\_MAX}$*($C_{S\_EXT\_MIN}$ − $C_{R\_EXT\_MAX}$) − 0.1*$C_{S\_EXT\_MIN}$ *($C_{S\_EXT\_MAX}$ - $C_{R\_EXT\_MIN}$)] /
      [0.9*$C_{S\_EXT\_MAX}$ - 0.1*$C_{S\_EXT\_MIN}$]   **Equation 16.**

If C_{OFS} ≥ 0pF

      then C_{R_INT} = C_{OFS} and C_{S_INT} = 0pF

      else C_{R_INT} = 0pF and C_{S_INT} is calculated as follows.

a = 0.8
b = 0.9*($C_{S\_EXT\_MAX}$ + $C_{S\_EXT\_MIN}$ − $C_{R\_EXT\_MAX}$) − 0.1*($C_{S\_EXT\_MAX}$ + $C_{S\_EXT\_MIN}$ - $C_{R\_EXT\_MIN}$)   **Equation 17a.**
c = 0.9*$C_{S\_EXT\_MAX}$ *($C_{S\_EXT\_MIN}$ − $C_{R\_EXT\_MAX}$) − 0.1*$C_{S\_EXT\_MIN}$ *($C_{S\_EXT\_MAX}$ - $C_{R\_EXT\_MIN}$)   **Equation 17b.**
C_{S_INT1} = [-b+√(b^2-4*a*c)]/2/a   **Equation 17c.**
C_{S_INT2} = [-b-√(b^2-4*a*c)]/2/a   **Equation 17d.**

If C_{S_INT1} ≥ 0pF then C_{S_INT} = C_{S_INT1} else C_{S_INT}= C_{S_INT2}

If C_{R_EXT} does not exist (C_{R_EXT} = 0pF) the equation 16 simplifies to following form.

C_{OFS} = C_{R_INT} = 0.8*$C_{S\_EXT\_MAX}$*$C_{S\_EXT\_MIN}$ / (0.9*$C_{S\_EXT\_MAX}$ - 0.1*$C_{S\_EXT\_MIN}$)   **Equation 18.**

Corresponding capacitance matrix register (REG$_{E3HEX}$ and REG$_{E4HEX}$) values (decimal) are calculated using equations 12 and 13 presented on page 24.

Optimal gain coefficient (K_{RATIO}) value is calculated as follows.

K_{RATIO} = 0.1 * ($C_{S\_EXT\_MIN}$ + C_{S_INT}) / ($C_{S\_EXT\_MIN}$ + C_{S_INT} − $C_{R\_EXT\_MAX}$ - C_{R_INT}) =   **Equation 19a.**
     = 0.9 * ($C_{S\_EXT\_MAX}$ + C_{S_INT}) / ($C_{S\_EXT\_MAX}$ + C_{S_INT} − $C_{R\_EXT\_MIN}$ - C_{R_INT})   **Equation 19b.**

Corresponding Gain register (REG$_{E5HEX}$) value (decimal) can be solved from the equation 10 presented on page 23 as follows.

GRDAC = 193.8/ K_{RATIO} (see table 6 for Gain register setting)   **Equation 20.**

Example 1: Only C_{S_EXT} varies and C_{R_EXT} does not exist (C_{R_EXT} = 0pF)

      $C_{S\_EXT\_MIN}$=4pF at sensed parameter (pressure, humidity etc.) minimum
      $C_{S\_EXT\_MAX}$=12pF at sensed parameter (pressure, humidity etc.) maximum
      $C_{R\_EXT\_MIN/MAX}$ = 0pF (no external reference capacitor) $\Rightarrow$

      C_{OFS} = 0.8*12pF*4pF/(0.9*12pF-0.1*4pF) = 3.69pF ≥ 0 $\Rightarrow$
      C_{R_INT} = C_{OFS} = 3.69pF and C_{S_INT} = 0pF
      K_{RATIO} = 0.1*(4pF+0pF)/(4pF-0pF-0pF-3.69pF) = 1.3

      REG$_{E3HEX}$ = OCDACS = (0pF/22pF)*255 = **0$_{DEC}$ (CS capacitor matrix)**
      REG$_{E4HEX}$ = OCDACR = (3.69pF/22pF)*255 ≈ **43$_{DEC}$ (CR capacitor matrix)**
      REG$_{E5HEX}$ = GRDAC = 193.8/1.3 = 149.08 ≈ **149$_{DEC}$ (Gain register)**

TRIMMING FOR SENSOR CAPACITANCE (continued)

Example 2: Only C_{S_EXT} varies but fixed C_{R_EXT} exists

$C_{S\_EXT\_MIN}$=9pF and $C_{R\_EXT\_MAX}$=10pF at sensed parameter (pressure, humidity etc.) minimum
$C_{S\_EXT\_MAX}$=14pF and $C_{R\_EXT\_MIN}$=10pF at sensed parameter (pressure, humidity etc.) maximum $\Rightarrow$

C_{OFS} = [0.9*14pF*(9pF-10pF)-0.1*9pF*(14pF-10pF)]/(0.9*14pF-0.1*9pF)= -1.38pF < 0 $\Rightarrow$
C_{R_INT} = 0pF
a = 0.8
b = 0.9*(14pF+9pF-10pF)-0.1*(14pF+9pF-10pF)= 10.4pF
c = 0.9*14pF*(9pF-10pF)-0.1*9pF*(14pF-10pF)= -16.2 pF^2
C_{S_INT1} = {-10.4pF+√ [(10.4pF)^2-4*0.8*(-16.2)pF^2]}/2/0.8= 1.406pF
C_{S_INT2} = {-10.4pF-√ [(10.4pF)^2-4*0.8*(-16.2)pF^2]}/2/0.8= -14.406pF $\Rightarrow$
C_{S_INT} = 1.406pF
K_{RATIO} = 0.1*(9pF+1.406pF)/(9pF+1.406pF-10pF-0pF) = 2.563

REG_{E3HEX} = OCDACS = (1.406pF/22pF)*255 = 16.29 $\approx$ **16_{DEC} (CS capacitor matrix)**
REG_{E4HEX} = OCDACR = (0pF/22pF)*255 = **0_{DEC} (CR capacitor matrix)**
REG_{E5HEX} = GRDAC = 193.8/2.563 = 75.61 $\approx$ **76_{DEC} (Gain register)**

Example 3: Both C_{S_EXT} and C_{R_EXT} vary but to opposite directions

$C_{S\_EXT\_MIN}$=10pF and $C_{R\_EXT\_MAX}$=14.5pF at sensed parameter (pressure, humidity etc.) minimum
$C_{S\_EXT\_MAX}$=14pF and $C_{R\_EXT\_MIN}$=10pF at sensed parameter (pressure, humidity etc.) maximum $\Rightarrow$

C_{OFS} = [0.9*14pF*(10pF-14.5pF)-0.1*10pF*(14pF-10pF)]/(0.9*14pF-0.1*10pF) = -5.23pF < 0 $\Rightarrow$
C_{R_INT} = 0pF
a = 0.8
b = 0.9*(14pF+10pF-14.5pF)-0.1*(14pF+10pF-10pF) = 7.15pF
c = 0.9*14pF*(10pF-14.5pF)-0.1*10pF*(14pF-10pF) = -60.7 pF^2
C_{S_INT1} = {-7.15pF+√ [(7.15pF)^2-4*0.8*(-60.7)pF^2]}/2/0.8 = 5.321pF
C_{S_INT2} = {-7.15pF-√ [(7.15pF)^2-4*0.8*(-60.7)pF^2]}/2/0.8 = -14.259pF $\Rightarrow$
C_{S_INT} = 5.321pF
K_{RATIO} = 0.1*(10pF+5.321pF)/(10pF+5.321pF-14.5pF-0pF) = 1.866

REG_{E3HEX} = OCDACS = (5.321pF/22pF)*255 = 61.68 $\approx$ **62_{DEC} (CS capacitor matrix)**
REG_{E4HEX} = OCDACR = (0pF/22pF)*255 = **0_{DEC} (CR capacitor matrix)**
REG_{E5HEX} = GRDAC = 193.8/1.866 = 103.86 $\approx$ **104_{DEC} (Gain register)**

The found REG_{E3HEX}, REG_{E4HEX} and REG_{E5HEX} trim register values need to be stored to corresponding non-volatile EEPROM addresses. In I2C communication these are $C3_{HEX}$, $C4_{HEX}$ and $C5_{HEX}$ but in SPI write communication the addresses are 43_{HEX}, 44_{HEX} and 45_{HEX} since in SPI write the MSB address bit is 0. See table 1 on page 9.

TEMPERATURE MODE

The MAS6510 has an internal temperature sensor for temperature measurement. The temperature sensor output is proportional to absolute temperature (PTAT). The temperature information is needed for temperature indication and temperature compensation.

The temperature measurement is started by writing configuration data to the measurement control register (E2/62_HEX). In the temperature measurement the internal regulator has to be enabled (TEMPREGEN=1) and the internal temperature sensor selected (SEL=10). The ratio and difference converter bit (XRC) selection does not have any influence on the result. Typically already the smallest over sampling ratio (OSR) selection 256 offers sufficient resolution for the temperature measurement.

The internal temperature sensor has offset and gain variation but small non-linearity (see Electrical Characteristics table). Depending on temperature measurement accuracy requirement the offset, the gain and the non-linearity all can be compensated by external calculations. In low precision the offset and gain calibration is sufficient but in high precision the second order non-linearity calibration can be included.

Linear temperature sensor model

The linear temperature measurement model for output code is following.

$$CODE = CODEFS \cdot \left(a + b \cdot \left(T - T_{REF} \right) \right) \qquad \textbf{Equation 21.}$$

The OSR selects full scale output code range value CODEFS. See ELECTRICAL CHARACTERISTICS for CODEFS_DIFF at different OSR values. If the temperature T is presented in °C and referenced to T_{REF}=0°C then the typical linearized temperature sensor model parameter values a and b are as follows.

a=0.38944
b=4.4329e-3

However it should be noted that the sensor has significant offset (parameter a) variation and also the gain (parameter b) has some variation and that the above values represent only typical values. The non-linearity temperature error after offset and gain calibration (best fit line) is typically <±0.5°C in the temperature range -40°C…+85°C.

2nd order temperature sensor model

For higher precision the 2nd order temperature measurement model for output code is following

$$CODE = CODEFS \cdot \left(a + b \cdot \left(T - T_{REF} \right) + c \cdot \left(T - T_{REF} \right)^2 \right) \qquad \textbf{Equation 22.}$$

If the temperature T is presented in °C and referenced to T_{REF}=0°C then the typical 2nd order temperature sensor model parameter values a, b and c are as follows.

a=0.38826
b=4.3967e-3
c=8.1098e-7

Above sensor model parameters are typical values which are subject to variations. The temperature error after offset, gain and 2nd order non-linearity calibration is typically <±0.1°C in the temperature range -40°C…+85°C.

VDD LEVEL MONITORING MODE

The MAS6510 has VDD level monitoring feature to measure supply voltage level which is useful especially in battery operated systems. In systems in which VDD can vary the VDD level monitoring could be also used to compensate VDD dependency.

The VDD level monitoring measurement is started by writing configuration data to the measurement control register (E2/62$_{HEX}$). In the VDD level

monitoring mode the regulator has to be disabled (TEMPREGEN=0) and VDD level monitoring selected (SEL=01). The ratio and difference converter bit (XRC) selection does not have any influence on the result.

Typically the smallest over sampling ratio (OSR) selection 256 offers sufficient resolution for the VDD level monitoring.

VDD level monitoring model

The VDD level monitoring model for output code is following.

$$CODE = CODEFS \cdot \left(a - \frac{b}{VDD} \right)$$

Equation 23.

The output has inverse relationship to supply voltage VDD. The OSR selects full scale output code range value CODEFS. See ELECTRICAL CHARACTERISTICS for CODEFS at different OSR values.

The typical VDD level monitoring model parameter values a and b are as follows.
a=1.6375
b=2.6942
Note that these parameter values are subject to about two percent variations.

The supply voltage VDD can be solved from the output result as follows.

$$VDD = \frac{b}{a - \dfrac{CODE}{CODEFS}}$$

Equation 24.

Figure 7 presents typical output code as function of supply voltage at OSR=256 (CODEFS=227328).
Figure 8 present supply voltage as function of output code at OSR=256 (CODEFS=227328).

APPLICATION INFORMATION
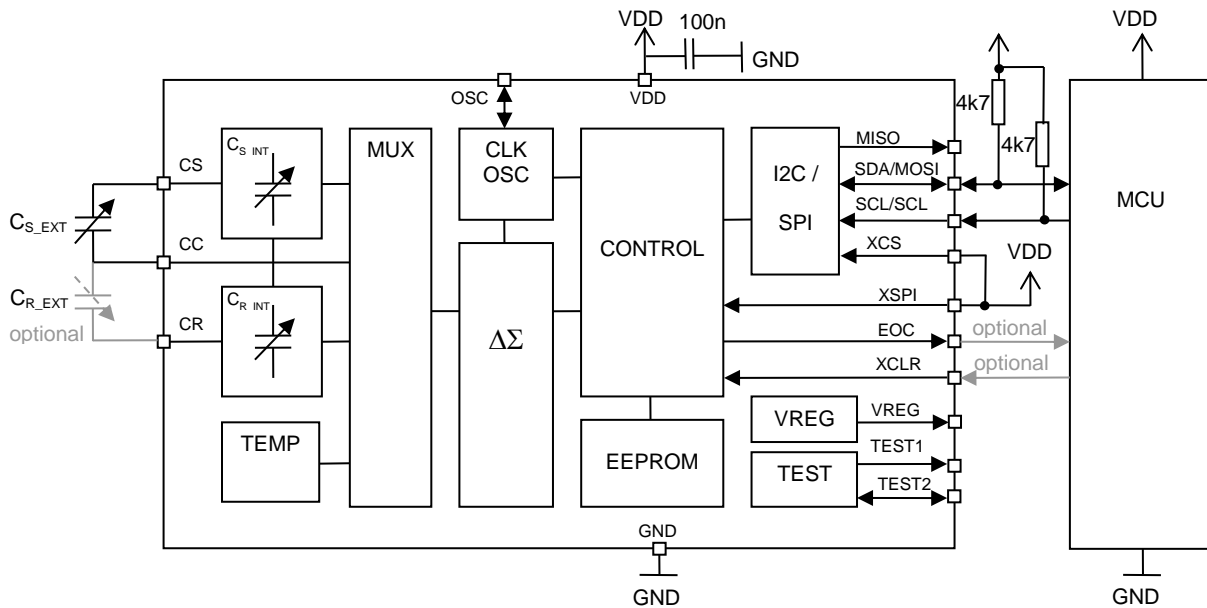

NOTE: It is recommended to use the XCLR reset feature to solve unexpected error state conditions.

Figure 9. MAS6510 configured for I2C bus communication

Note: MAS6510 has an effective ESD clamp protection structure that can be triggered if the VDD rises too fast. Therefore, it's recommended to use a supply decoupling capacitor having a value of 100nF or higher to slow down the VDD rise time.

Note: The voltage regulator output VREG does not require external capacitor as shown in figure 9. However, if an output capacitor is wanted to be used for extra filtering the capacitor value should not be higher than 6.8nF.

Figure 9 presents MAS6510 application circuit using I2C bus.

Resolution Improvement – Averaging

An averaging technique can be used to remove conversion errors caused by noise and thus improve measurement resolution. By doing several A/D conversions and calculating the average result it's possible to average out noise. Theoretically the noise is reduced by a factor $\sqrt{N}$ where N is the number of averaged samples. A/D converter nonlinearities cannot be removed by averaging.

MAS6510 IN QFN-16 4x4x0.75 PACKAGE (SAMPLES ONLY)
Top Marking Information:
MAS6510 = Product Number,
VVV = Version Number
YYWW = Year Week
XXXXX = Lot Number

QFN-16 4x4x0.75 PIN DESCRIPTION

Pin Name	Pin	Type	Function	Note
XCS	1	DI	Chip Select (SPI)	
XSPI	2	DI	SPI / I2C Bus Selection SPI: XSPI=low I2C: XSPI=high	
MISO	3	DO	Master Input Slave Output (SPI)	
VDD	4	P	Power Supply Voltage	
SDA_MOSI	5	DI/O	Serial Bus Data (I2C) Master Output Salve Input (SPI)	
SCL_SLCK	6	DI	Serial Bus Clock (I2C / SPI)	
XCLR	7	DI	Master Reset	1
VREG	8	AO	Voltage Regulator Output 1.8V	
CR	9	AO	Reference Capacitance Pin	
CC	10	AI	Common Capacitance Pin	
CS	11	AO	Sensing Capacitance Pin	
GND	12	G	Power Supply Ground	
OSC	13	DI/DO	Oscillator Input / Output	
TEST2	14	AI/O	Test pin 2	
TEST1	15	DO	Test pin 1	
EOC	16	DO	End of Conversion	

P = Power, G = Ground, DO = Digital Output, , DI = Digital Input, AO = Analog Output, AI = Analog Input
Note 1: The XCLR pin has internal pull up to VDD. If not used the XCLR pin can be left unconnected.
Note: The exposed pad of the QFN package should be connected to the GND.

PACKAGE (QFN-16 4x4x0.75) OUTLINE (SAMPLES ONLY)
Symbol	Min	Nom	Max	Unit
PACKAGE DIMENSIONS				
A	0.700	0.750	0.800	mm
A1	0.000	0.020	0.050	mm
A3		0.203 REF		mm
b	0.250	---	0.350	mm
D	3.950	4.000	4.050	mm
D2 (Exposed.pad)	2.700	---	2.900	mm
E	3.950	4.000	4.050	mm
E2 (Exposed.pad)	2.700	---	2.900	mm
e		0.650 BSC		mm
L	0.350	---	0.450	mm

Dimensions do not include mold or interlead flash, protrusions or gate burrs.

ORDERING INFORMATION

Product Code	Product	Description
MAS6510EA1WAD00	Capacitive Sensor Signal Interface IC	Tested inked wafer, thickness 370 µm
MAS6510EA1WAD05	Capacitive Sensor Signal Interface IC	Bare die in tray, thickness 370 µm
MAS6510EA1WAB05	Capacitive Sensor Signal Interface IC	Bare die in tray, thickness 180 µm
MAS6510EA1Q1708	Capacitive Sensor Signal Interface IC	QFN-16 4x4x0.75, Pb-free, RoHS compliant, loose components (samples only)
